Working Papers

1. **"Learning Traps."** 2025. **Revise and Resubmit, American Journal of Political Science.**

When constituents are uncertain about whether leaders' policy preferences align with their interests, policy choices generate a tradeoff between payoffs and information. Leaders can experiment with their preferred policy, but if the outcome is bad, constituents learn this and threaten office removal. I use a repeated model of political agency to analyze how this tradeoff shapes long-lived, term-unlimited leaders' policy choices. When there is uncertainty about the optimal policy for constituents, leaders implement "learning traps": spatially intermediate policies that halt learning about what the best policy is. They experiment only when their preferences are very likely to be aligned with constituents, a contrast to the "gambling for resurrection" logic ubiquitous in the literature. I provide a case study that examines how the 1861 reforms ending serfdom in Imperial Russia represented the logic of a "learning trap" and illustrate additional applications of the model to political contagion and economic policymaking.

2. **"Persuasion with Partisanship: The Informational Content of Policymaking with Application to US Governors."** 2025.

I study a model where a political executive's policy agenda generates information about her ability. Since policies favoring a single party are harder to pass, the partisanship of an agenda influences what success or failure of passage communicates about ability. The model delivers a U-shape relationship between an executive's ex-ante winning chances

and her agenda's partisanship. Executives likely to lose pursue partisan policies to save their winning chances. Those likely to win embrace partisan policies whose failure can be blamed on the legislature. Those in the middle pursue bipartisan policies to secure reelection. I use these insights to analyze the partisanship of U.S. governors' policy proposals from 1990-2020, showing that while partisanship has risen on average, there is sizeable variation at the governor level. I interpret these variations as responses to electoral incentives by testing the model and showing a U-shaped relationship between partisanship and approval ratings.

3. **"Misconduct in Organizations."** With Kim Sarnoff. 2025.

We study how policies that disincentivize misconduct in organizations can generate changes in abusers' behaviors that negatively impact victims. We describe a model where "managers" choose to commit harmful actions of varying intensities against "employees," who can report these actions as "misconduct." We show that when the marginal disutility from managers' actions is particularly small, increasing the ease of reporting misconduct, the severity of punishment for managers, or the efficacy of investigation technology may in fact harm employees. These policies may motivate managers to commit harmful actions that employees do not want to report or induce managers to opt out of interacting with employees altogether. We provide a dynamic extension where reports generate precedents for the organization and employees, showing that the model converges to a steady state where employees are worse off than initially and harmful actions are never punished.

4. **"The Twin Puzzles of U.S. Productivity Growth Dynamics: A New Interpretation."** With Robert J. Gordon. 2025. NBER WP 30267, CEPR DP19569.

This paper provides a unified framework that resolves recent puzzles in U.S. productivity growth that we show are interrelated. First, why was productivity growth in the 2010-19 decade the slowest of any decade in U.S. history? Second, why did the cyclical-ity of productivity growth change from procyclical in 1950-85 to acyclical in 1986-2006 and then back to procyclical in 2010-19? Third, why was productivity growth strongly countercyclical in the recessions of 2008-09 and 2020? The fundamental dynamic driving cyclical productivity fluctuations originates in the gradual adjustment of hours of work to demand-driven output fluctuations due to the costs of hiring and firing labor. Since productivity growth is a residual by definition, equal to output growth less hours growth, productivity growth immediately jumps in response to an upward output movement because hours are slow to respond and then falls back in subsequent quarters as hours complete their adjustment. We are able to explain the temporary 1986-2006 disappearance of procyclicality and its reappearance after 2009 as the result of changes in the standard deviation and serial correlation of output changes. We explain countercyclical productivity surges in 2008-09 and 2020 by showing that business firms in those two episodes overreacted with "excess layoffs," cutting hours in response to the sharp output decline with a much higher elasticity than normal. By coupling these excess layoffs with a post-recession rehiring effect that boosted hours growth and depressed productivity growth for 2010-19, our regression analysis explains why productivity growth on average was so slow during that decade. If this recession/rehiring effect had not occurred, productivity growth in the 2010-19 decade would have been 2.1 percent per year instead of 1.2 percent, suggesting

that concern about U.S. “secular stagnation” has been overstated.

Selected Work in Progress

1. “Push vs. Pull Funding and Optimal Innovation Policy” (slides available on request)

Suppose a funder can pay multiple firms that attempt to develop a socially beneficial innovation. If she wants to maximize the probability of developing the innovation, should she pursue “push funding” — such as unconditional research grants — or “pull-funding” — such as prizes or advance-market-commitments? I derive generic conditions in a heterogeneous, multi-firm setting under which pull funding is cheaper than push for a given target probability of success. While pull funding allows firms to capture information rents, it also allows funders to screen in highly efficient firms. Pull is cheaper if the target probability is modest or firm markets are sufficiently large. I provide practical tools for policymakers interested in designing push and pull policies.

2. “Learning from Blackboxes”

Consider a principal who contracts an agent for a recommendation. The agent utilizes a model and data to provide this recommendation. However, this model is a “blackbox” for the principal; she does not understand the data or the model. I provide bounds for learning from these “blackboxed” models, and show that the value of black-boxed models for the principal depends on the structure of her objective function. I explore applications of these findings to the adoption of artificial intelligence in the workplace and subcontracting in organizations.

3. “Inference from Choices and Spatial Differentiation” (slides available upon request)

Producers or politicians can differentiate themselves horizontally (in product/policy spaces) or vertically (in quality space). Consumers and voters make inferences about products or politicians by observing others’ choice data — such as who won an election or who purchased a product — but without observing others’ information. I show how career concerns distort producers’ (or politicians’) willingness to horizontally differentiate themselves from the competition, particularly in settings of dynamic choice, leading to convergence on inefficient policies.

4. “Model-Based Inference” (with Kim Sarnoff)

How do everyday Americans make inferences about causal processes underlying economic outcomes? This experimental project uses a “coefficient weight” method to elicit how participants create mental models that organize data.
